

ABSTRACT OF THE DISCLOSURE

Electronic tickets are triggered by a trigger message,
out of a standby state, for the determination of used
capacity. In order to further reduce energy requirements, or
5 to increase the autonomy of the tickets, a trigger message
recognition and selection is disclosed, whereby firstly a
trigger message is detected in a receiver and, subsequently,
when information contained in a detected trigger message is
destined for the relevant ticket, a processor module is
10 activated by means of a switch. In a preferred embodiment,
the activation is a multi-stage form, in which a digital
filter is arranged between the receiver and processor module
which can also be activated by a switch. The switch for
activating the process module may be operated by the digital
15 filter.
